ABSTRACT

Proteins of the Bcl-2 family are key regulators of caspase activation and apoptosis. Some members of this family, notably Bcl-2 and Bcl-xL, are overexpressed in cancer cells, which have been associated with chemoresistance. We have designed and synthesized a small molecule inhibitor of Bcl-2, named YC137, and studied its role in cancer cells. In vitro studies showed that YC137 inhibits the binding of the Bid BH3 peptide to Bcl-2, thus disrupting an interaction essential for the antiapoptotic activity of Bcl-2. This inhibitor induces apoptosis of hematopoietic progenitors overexpressing Bcl-2 but not Bcl-xL and breast cancer cells that express high levels of Bcl-2. On the contrary, a variety of normal primary cells, including CD34+ progenitors, myoblasts, and peripheral blood mononuclear cells, do not respond to the inhibitor. A breast cancer cell line resistant to YC137 was generated. Analysis of resistant cells revealed a reduced expression of Bcl-2, which correlated with low activation of signal transducer and activator of transcription-3 (Stat3) and reduced expression of the human epidermal growth factor receptor-2 (HER2). Of note, YC137-resistant cells were more sensitive to apoptosis induced by chemotherapy. Because HER2 has not been linked previously to the Stat3-Bcl-2 transcriptional pathway, we additionally confirmed that specific blockade of HER2 in breast cancer cells resulted in down-regulation of Stat3 activity and reduced levels of Bcl-2. Consistently, HER2 blockade led to YC137 resistance. These data provide evidence for the selective killing of tumor cells by YC137 and represent the first example of in vitro selection of cancer cells refractory to a Bcl-2 inhibitor.

INTRODUCTION

The expression of genes that regulate apoptotic cell death plays an important role in determining the sensitivity of tumor cells to chemotherapy. High expression of the antiapoptotic protein Bcl-2 is found in a number of human hematologic malignancies and solid tumors (1, 2). The functional blockade of Bcl-2 or other antiapoptotic proteins, such as Bcl-xL, could either induce apoptosis in cancer cells or sensitize these cells for chemotherapy. To this end, it has been reported that down-regulation of Bcl-2 by antisense oligonucleotides induces apoptosis in myeloid leukemia cells, breast and colorectal carcinomas, and lung cancer cells among others, even in the presence of other antiapoptotic genes (3–6). In other cell systems (i.e., MCF7 breast cancer cells, HL-60 myeloid leukemia cell line, and myeloma cells), the use of a Bcl-2 antisense oligonucleotide sensitizes tumor cells to chemotherapeutic drugs (3, 7, 8). Consequently, antiapoptotic members of the Bcl-2 family have attracted intensive interest in drug discovery to develop a new class of anticancer agents (9). BH3-mediated homodimerizations and heterodimerizations play a key role in regulating the apoptotic activity of Bcl-2 family members (10). Structural analysis of the Bcl-xL-Bak BH3 peptide complex (11) and more recently the Bcl-2 protein (12) has made possible the identification of small molecules that inhibit the interaction between the BH3 domain of proapoptotic proteins and the hydrophobic cleft of Bcl-2 or Bcl-xL (13–16). Some of these compounds have been shown to reduce cell viability in cancer cell lines, which suggests that they could lead to the development of new therapeutic agents. However, it has not elucidated the activity of these small molecules on normal cells, such as hematopoietic progenitors and epithelial cells, which are commonly affected after chemotherapy.

The clinical success of small molecule kinase inhibitors has led to the notion that other selective inhibitors may have significant activity against a range of human malignancies (17). However, clinical resistance to these agents has been reported, and it is believed that preexisting mutant cells are selected by the agent to which the mutation confers resistance (18). By analogy, Bcl-2 inhibitors could select for resistant cells. Consequently, research should focus on defining the mechanisms of resistance, so that the emergence of resistant clones might be prevented.

In this study, we show that a novel small molecule inhibitor of Bcl-2, YC137, induces apoptosis in breast cancer cells that express high levels of Bcl-2 but does not have any effect on normal hematopoietic progenitors, peripheral blood mononuclear cells (PBMCs), small intestine epithelial cells, and myoblasts. Furthermore, tumor cells that evade the apoptotic effects of YC137 down-regulate Bcl-2 and become more sensitive to conventional chemotherapy.

MATERIALS AND METHODS

Cell Lines and Primary Cells. Breast cancer cell lines MDA-MB435L (lung metastatic variant of MDA-MB435), MDA-MB435B (brain metastatic variant of MDA-MB435), MDA-MB231, MCF7, and SKBR3 were cultured as described previously (19). SUM185, SUM159, and SUM229 were incubated in DMEM/Ham’s F-12 (Biochrom KG, Berlin, Germany), supplemented with 5% fetal calf serum, 5 μg/mL insulin, and 1 μg/mL hydrocortisone (both from Sigma, St. Louis, MO). Normal small intestine FHs cells were grown in DMEM/Ham’s F-12 with 10% fetal calf serum, 10 ng/mL cholera toxin, 5 μg/mL transferrin, 5 μg/mL insulin, and 100 ng/mL hydrocortisone (Sigma). HCD-57 and PL5.12 hematopoietic cells and their derivative cell lines transfected with Bcl-2 or Bcl-xL were cultured as described previously (20).

PBMCs were obtained from normal donors. CD34+ cells were selected from the PBMC population of donors undergoing mobilization for allogeneic progenitor cell transplantation as described previously (21). All of the donors signed informed consent according to Guidelines from the Committee for the Protection of Human Subjects at the University Hospital Marques de Valdecilla. Myoblasts were obtained from the Cell Therapy Unit, at the University Clinic of Navarra following a protocol described previously (22). In some experiments, MB435B cells were treated with the recombinant humanized antihuman epidermal growth factor receptor (HER2) monoclonal antibody trastuzumab (F. Hoffmann-La Roche, Basel, Switzerland) and then additionally analyzed for the expression of Bcl-2.

Chemical Synthesis of YC137. Briefly, 1.35 g (5.95 mmol) of 2,3-dichloro-1,4-naphthoquinone were dissolved in 20 mL of 1,4-dioxane, and
then 1 g (5.95 mmol) of 4-hydroxyphenylthiourea was added. The mixture was refluxed for 20 minutes. When the color of the reaction mixture turned to deep purple, 20 mL of EtOH and 1.344 g (12 mmol) of 1,4-diazabicyclo(2,2,2)octane (Dabco) were added and refluxed for 5 hours. The reaction mixture was then cooled down to room temperature, and the solvent was removed under vacuum. Then, the important intermediate (deep violet solid) was purified by flash column chromatography. To a solution of 10 mL of dichloromethane and 110 mg (0.53 mmol) of N-methyl-formate-L-methionine, 110 mg (0.53 mmol) of dicyclohexylcarbodiimide were added in ice-cold bath, followed by the addition of 142 mg (0.44 mmol) of the intermediate. Then, the reaction mixture was allowed to warm up to room temperature and stirred for 16 hours. The solid of the reaction mixture was filtered out and washed with brine, dried over sodium sulfate, and purified via flash chromatography.

YC137 was solubilized at 10 mmol/L in dimethylsulfoxide and kept at −20°C in the dark until use. This stock solution was diluted >10^4-fold for both binding assays and cell culture experiments.

**Competitive Fluorescence Polarization Binding Assay.** A sensitive and quantitative in vitro binding assay using a fluorescence polarization-based method was developed and used to determine the binding affinity of YC137 to Bcl-2 protein. For this assay, 6-carboxy fluorescein succinimidyl ester was coupled to a 21-residue Bid peptide (Flu-QEDIRINARHLAQVQDSMDR), which binds with high affinity to Bcl-2 protein (K_i = 47 nmol/L).

Fluorescence polarization experiments were performed in Dynex 96-well, black, and round-bottomed plates (Fisher Scientific, Hampton, NH) using the Ultra Plate Reader (Tecan U.S., Inc., Research Triangle Park, NC). YC137, diluted in assay buffer, was incubated with recombinant His-fused soluble Bcl-2 protein (120 nmol/L) and Flu-Bid peptide (5 nmol/L). It is worthy of note that the assay buffer conditions have a great influence on the binding affinity of YC137. Thus, we tried a number of assay conditions until consistent results were obtained in three independent experiments with a buffer containing 50 mmol/L Bis-Tris (pH 7.4) and 0.01% bovine γ globulin. The plates were mixed and incubated at room temperature for 4 hours to reach equilibrium. Curve fitting was performed using GraphPad Prism software. A nonslabed Bid BH3 peptide was used as the positive control. The K_i values were calculated using an automatically developed equation for fluorescence polarization-based binding assays (23). For determination of the binding affinity to Bcl-xL protein, we used human Bcl-xL recombinant His-tagged protein without the COOH-terminal hydrophobic tail (120 nmol/L) and Flu-Bid peptide (5 nmol/L), and the competitive binding assay was performed in the same way as for the Bcl-2 protein.

**Transfection and Flow Cytometry Analysis.** CD34^+ progenitors (1 × 10^6 cells) were cotransfected with 1 μg of a vector encoding enhanced green fluorescence protein (pEGFP-C1, BD Biosciences, Palo Alto, CA) and 4 μg of pSFFV-Bcl-2 (24) by using the human CD34 cell nucleofector kit (Amaxa, Cologne, Germany). After nucleofection, cells were cultured for 16 h with or without stem cell factor and interleukin-3 at a final concentration of 100 ng/mL. After 0.29 μmol/L YC137 was added to the culture, and after 24 hours of incubation, apoptotic cells were detected, within the EGFP black, and round-bottomed plates (Fisher Scientific, Hampton, NH) using the Ultra Plate Reader (Tecan U.S., Inc., Research Triangle Park, NC).

**RESULTS**

Characterization of a Small Molecule Inhibitor of Bcl-2. We have used a structure-based computer screening strategy to discover novel small molecule inhibitors that bind to the crucial BH3-binding groove of Bcl-2 protein (16). On the basis of the structure of initial lead compounds, we have designed and synthesized new analogues to improve their binding affinity and cellular activity. One of these compounds, YC137 (Fig. 1A), was selected for binding assays and additional biological studies to determine its specificity and activity.

The binding affinity of YC137 to Bcl-2 protein was analyzed using fluorescence polarization-based methods (Fig. 1B). We determined that YC137 has a K_i value of 1.3 μmol/L when assayed in Bis-Tris buffer. As a positive control, the 21-residue Bid-BH3 peptide was subjected to the same binding assay conditions (Fig. 1B), and we determined a K_i value of 54 nmol/L. Using a similar fluorescence polarization-based method for Bcl-xL, we determined that YC137 has a K_i value >100 μmol/L (data not shown), suggesting that this small molecule preferentially binds to Bcl-2 protein.

A model of Bcl-2 in complex with YC137 was generated by docking YC137 into the BH3 domain-binding pocket of Bcl-2 (Fig. 2). The three-dimensional structure of the Bcl-2 protein (isoform-2) was obtained from the Protein Data Bank (entry 1GIH), and molecular docking was performed with the GOLD program (version 2.1, distributed by Cambridge Crystallographic Data Center). According to this predicted binding model, the tri-cyclic moiety of YC137 occupies two hydrophobic sites in the Bcl-2-binding pocket and forms hydrogen bonds with residues Arg107, Tyr108, Arg146, and Tyr202 of the Bcl-2 protein.

YC137 Induces Apoptosis of Bcl-2-Dependent Cells. To confirm the specificity of YC137 for the Bcl-2 protein in cellular models, we analyzed its activity in cells dependent on Bcl-2 or Bcl-xL for survival. FL5.12 hematopoietic progenitors and HCD-57 erythroid cells...
The affinity for Bcl-2 was measured by a competitive fluorescence polarization assay. Each presence of increasing concentrations of YC137 or unlabeled Bid peptide, and the binding soluble Bcl-2 protein was incubated with a fluorescein-labeled Bid-BH3 peptide in the represents the mean point SD of at least three independent experiments.

YC137 Correlates with the Levels of Bcl-2. We have shown previously that a metastatic variant of an estrogen receptor-negative breast cancer cell line, MB435B, expresses high levels of Bcl-2 as compared with the parental cell line MB435 (19). Thus, we studied the effect of YC137 on these cells and other breast cancer cell lines (MB435L, MB231, SKBR3, MCF7, SUM159, SUM185, and SUM229) with different levels of Bcl-2 expression. Interestingly, the expression level of Bcl-2 correlated with the apoptotic response to the inhibitor (Fig. 4, A and B). Thus, MB435B and SUM159 cells, which express the highest levels of Bcl-2 protein, showed also the strongest apoptotic response after 20 hours of treatment with YC137. To determine whether YC137 induces apoptosis via caspase activation, we treated MB435B cells with the inhibitor in the presence of a cell-permeable fluorescent peptide that irreversibly binds to activated caspase 9, a caspase strongly associated with chemotherapy-induced apoptosis. As shown in Fig. 4C, after 2 hours of culture with the inhibitor, activated caspase 9 was present in the great majority (>85%) of tumor cells. Furthermore, we studied whether YC137 induces the release of cytochrome c from mitochondria, which is needed for caspase 9 activation. Analysis of soluble and heavy membrane fractions by Western blot revealed that YC137 induced cytochrome c release (present in soluble fraction) in MB435B cells treated with the inhibitor for 24 hours (Fig. 4D).

Normal Primary Cell Survival Is Not Modified by Treatment with YC137. A key issue to validate a new chemotherapeutic drug is to determine its tumor specificity. For this purpose, we treated normal small intestine epithelial cells (FHs), primary myoblasts, and PBMCs with YC137. Cells were incubated with increasing concentrations of YC137 (0.1 to 0.5 μmol/L) for 20 hours and then analyzed for the presence of histone-associated DNA fragments. As shown in Fig. 5A, apoptosis was not detected in these cells at any of the concentrations tested, whereas MB435B, used here as a positive control, reached the highest level of apoptosis at 0.3 μmol/L YC137.

Ex vivo expanded peripheral blood progenitor cells have been proposed as a source of hematopoietic support to decrease or eliminate the period of neutropenia after high-dose chemotherapy (28). However, this procedure will only be advantageous if contaminating tumor cells are not expanded concomitantly. This model served us to additionally analyze the specificity of the Bcl-2 inhibitor. We cocultured defined numbers of MB435B cells with CD34+ cells selected from normal donors in the presence of 0.4 μmol/L YC137. By 20 hours of treatment, 27% of MB435B cells (CD34+ cell population) were annexin V positive as determined by flow cytometry analysis,

are dependent on IL-3 and erythropoietin, respectively. In the absence of the growth factor, these cells stop proliferation and undergo apoptosis. However, apoptosis induced by IL-3 or erythropoietin deprivation can be inhibited or delayed in cells overexpressing Bcl-2 or Bcl-xL (20). On the basis of this, FL5.12 and HCD-57 transfected with pSFFV-Bcl-2 and an EGFP-containing vector. After transfection, cells were cultured in the absence of IL-3 and stem cell factor, indicating the period of neutropenia after high-dose chemotherapy (28).

To demonstrate the specificity for Bcl-2 in a more physiologically relevant model, we transiently cotransfected CD34+ progenitors with pSFFV-Bcl-2 and an EGFP-containing vector. After transfection, cells were cultured in the presence or absence of IL-3 and stem cell factor as survival factors. Then, YC137 was added to the culture and incubated for 24 hours. As shown in Fig. 3D, YC137 did not induce apoptosis of Bcl-2-transfected cells (EGFP+) cultured with the survival factors, most likely because of the expression of other antiapoptotic proteins, such as Bcl-xL. On the contrary, the Bcl-2 inhibitor increased the percentage of apoptosis ~2-fold when transfected cells were cultured in the absence of IL-3 and stem cell factor, indicating that YC137 induces apoptosis of CD34+ progenitors when viability of these cells is mainly dependent on Bcl-2, which is consistent with our previous data.

Apoptosis of Breast Cancer Cells Induced by Treatment with YC137 Correlates with the Levels of Bcl-2. We have shown previously that a metastatic variant of an estrogen receptor-negative breast cancer cell line, MB435B, expresses high levels of Bcl-2 as compared with the parental cell line MB435 (19). Thus, we studied the effect of YC137 on these cells and other breast cancer cell lines (MB435L, MB231, SKBR3, MCF7, SUM159, SUM185, and SUM229) with different levels of Bcl-2 expression. Interestingly, the expression level of Bcl-2 correlated with the apoptotic response to the inhibitor (Fig. 4, A and B). Thus, MB435B and SUM159 cells, which express the highest levels of Bcl-2 protein, showed also the strongest apoptotic response after 20 hours of treatment with YC137. To determine whether YC137 induces apoptosis via caspase activation, we treated MB435B cells with the inhibitor in the presence of a cell-permeable fluorescent peptide that irreversibly binds to activated caspase 9, a caspase strongly associated with chemotherapy-induced apoptosis. As shown in Fig. 4C, after 2 hours of culture with the inhibitor, activated caspase 9 was present in the great majority (>85%) of tumor cells. Furthermore, we studied whether YC137 induces the release of cytochrome c from mitochondria, which is needed for caspase 9 activation. Analysis of soluble and heavy membrane fractions by Western blot revealed that YC137 induced cytochrome c release (present in soluble fraction) in MB435B cells treated with the inhibitor for 24 hours (Fig. 4D).

Normal Primary Cell Survival Is Not Modified by Treatment with YC137. A key issue to validate a new chemotherapeutic drug is to determine its tumor specificity. For this purpose, we treated normal small intestine epithelial cells (FHs), primary myoblasts, and PBMCs with YC137. Cells were incubated with increasing concentrations of YC137 (0.1 to 0.5 μmol/L) for 20 hours and then analyzed for the presence of histone-associated DNA fragments. As shown in Fig. 5A, apoptosis was not detected in these cells at any of the concentrations tested, whereas MB435B, used here as a positive control, reached the highest level of apoptosis at 0.3 μmol/L YC137.

Ex vivo expanded peripheral blood progenitor cells have been proposed as a source of hematopoietic support to decrease or eliminate the period of neutropenia after high-dose chemotherapy (28). However, this procedure will only be advantageous if contaminating tumor cells are not expanded concomitantly. This model served us to additionally analyze the specificity of the Bcl-2 inhibitor. We cocultured defined numbers of MB435B cells with CD34+ cells selected from normal donors in the presence of 0.4 μmol/L YC137. By 20 hours of treatment, 27% of MB435B cells (CD34+ cell population) were annexin V positive as determined by flow cytometry analysis,
whereas >95% of hematopoietic progenitors (CD34+ cell population) were viable annexin V-negative cells (Fig. 5B).

As shown in Fig. 4C and Fig. 5B, there is a difference in the percentage of apoptotic cells between annexin V and activated caspase 9 assays in MB435B cells treated with YC137. This may reflect the fact that activation of caspase 9 measures early apoptosis, whereas annexin V measures late apoptosis, and that both methods assess different cellular responses to apoptosis.

**YC137-Resistant Breast Cancer Cells Down-Regulate the Expression of Bcl-2.** Resistance to small molecules that inhibit defined tyrosine kinases has been reported in both cell lines and primary cells (17). As a first step to know whether tumor cells may develop resistance to Bcl-2 inhibitors, we cultured MB435B cells with increasing concentrations of YC137. After 3 months of culture, a MB435B subline growing at 0.225 μmol/L YC137 (a lethal concentration for parental cells) was isolated. Comparative genomic hybridization analysis revealed no chromosome abnormalities (deletions or amplifications) in the resistant variant (data not shown). Interestingly, these cells had low expression of Bcl-2 at the protein and mRNA level (Fig. 6, A and B); however, the expression of Bcl-xL was the same as that of the parental cell line. We have described previously that Bcl-2 is transcriptionally regulated by Stat3 in MB435B cells (19). Therefore, we analyzed the DNA binding activity of this transcription factor and found a reduced constitutive activation as measured by electrophoretic...
mobility shift assay (Fig. 6C). As Bcl-2 contributes to interfere with the therapeutic action of many chemotherapeutic drugs, we asked whether a reduced expression of Bcl-2 may render YC137-resistant cells more sensitive to chemotherapy-induced apoptosis. To answer this question, we treated parental and resistant MB435B breast cancer cells with either paclitaxel or adriamycin. Fig. 6D shows that after a 16-hour treatment, YC137-resistant MB435B cells were more sensitive to chemotherapy-induced apoptosis than parental cells, although this difference was more pronounced in Adriamycin-treated cells. The level of apoptosis induced by treatment with Adriamycin was as much as eight times higher in the resistant variant than in MB435B cells (Fig. 6D). Similar results were obtained with individual YC137-resistant clones (data not shown).

HER2 Is Down-Regulated in YC137-Resistant MB435B Cells.

We have described that EGFR is involved in activation of the Stat3-Bcl-2 transcriptional pathway in MB435B cells (19). Thus, we studied the expression of this membrane receptor in the YC137-resistant subline. However, the levels of EGFR mRNA are the same in both parental and resistant cells (Fig. 7A). Constitutively activated Stat3 is also correlated with up-regulation of HER2, another member of the EGFR family. Interestingly, we found that the mRNA and protein levels of HER2 were clearly down-regulated in the resistant variant (Fig. 7A and B). This result prompted us to analyze whether HER2 may regulate the expression of Bcl-2 via Stat3. To address this issue, we treated MB435B cells with trastuzumab, a blocking antibody against HER2, and then analyzed the DNA-binding activity of Stat3 and the Bcl-2 expression. As shown in Fig. 7C, treatment of MB435B with trastuzumab for 6 hours significantly reduced the activation of Stat3, as determined by electrophoretic mobility shift assay, which continued to decrease by 12 hours of treatment. This pattern of Stat3-DNA binding complex formation correlated with the protein and mRNA levels of Bcl-2, which were clearly down-regulated after 24 hours of treatment with trastuzumab (Fig. 7D). Furthermore, consistent with our previous data, trastuzumab-treated cells became more resistant to YC137. Pretreatment with trastuzumab for 24 hours reduced ~2-fold the number of apoptotic MB435B cells cultured in the presence of YC137, as determined by flow cytometry with FITC-labeled annexin V (Fig. 7E).

To additionally confirm this transcriptional pathway in a more direct way, we analyzed the effect of a constitutively activated form of Stat3 (Stat3-C) on the Bcl-2 expression in MB435B treated with trastuzumab. Cells were cotransfected with a vector expressing EGFP and vector encoding Stat3-C. After 36 hours of transfection in the presence of trastuzumab, the control cells had significantly reduced the expression of Bcl-2 (~35%), whereas those expressing Stat3-C had no variation in the levels of Bcl-2 as determined by flow cytometry (Fig. 7F).

**DISCUSSION**

Most of the currently available small molecule inhibitors are designed to block the enzymatic activity of key proteins in cancer cells (17), and there are very few examples of inhibitors that disrupt protein–protein interactions. Bcl-2 family members play key roles in the regulation of apoptosis and may contribute to cancer development and resistance to chemotherapy, which have attracted intensive inter-
est in the discovery of small molecules that inhibit the activity of antiapoptotic proteins of this family, mainly Bcl-2 and Bcl-x<sub>L</sub> (13–16). Here, we have designed and synthesized an inhibitor of Bcl-2, YC137, which shows high Bcl-2-binding activity. However, it is much less effective in binding to Bcl-x<sub>L</sub>. This is consistent with our data, which demonstrate that YC137 selectively induces apoptosis in breast cancer cells with high levels of Bcl-2. Interestingly, the concentration of YC137 needed for the selective killing of tumor cells is >20 times lower than that reported for the other Bcl-2/Bcl-x<sub>L</sub> inhibitors. Of note, a complete apoptotic response was achieved at concentrations about four to six times lower than the Ki value of YC137. There are two main explanations for this discrepancy: (1) the concentration of Bcl-2 protein used in our fluorescence polarization-based binding assays is 120 nmol/L, which might be considerably higher than the cellular concentration of Bcl-2, and (2) YC137 has a poor binding affinity in our binding assay conditions, and consequently, it is possible that the binding affinity of YC137 was underestimated. The effectiveness of this inhibitor in hematopoietic precursors that become dependent on Bcl-2 for survival suggests that the sensitivity to Bcl-2 inhibitors will be given not only by the levels of Bcl-2 but also the contribution of this antiapoptotic protein to the overall survival of particular tumor cells. Consistently, apoptosis can be induced in a number of tumor cell lines by decreasing the amount of Bcl-2 protein (4, 29). Anticancer drugs used in chemotherapy for tumors and leukemias cause severe toxicity in normal tissues, leading to side effects such as myelosuppression (30). Thus, it is of particular interest our finding that normal cells, including a small intestine epithelial cell line (FHs), myoblasts, PBMCs, and CD34<sup>+</sup> hematopoietic progenitors, are not sensitive to YC137. A likely explanation is that Bcl-2 is transcriptionally regulated by Stat3 (13–16). Here, we have designed and synthesized an inhibitor of Bcl-2, YC137, which shows high Bcl-2-binding activity. However, it is much less effective in binding to Bcl-x<sub>L</sub>. This is consistent with our data, which demonstrate that YC137 selectively induces apoptosis in breast cancer cells with high levels of Bcl-2. Interestingly, the concentration of YC137 needed for the selective killing of tumor cells is >20 times lower than that reported for the other Bcl-2/Bcl-x<sub>L</sub> inhibitors. Of note, a complete apoptotic response was achieved at concentrations about four to six times lower than the Ki value of YC137. There are two main explanations for this discrepancy: (1) the concentration of Bcl-2 protein used in our fluorescence polarization-based binding assays is 120 nmol/L, which might be considerably higher than the cellular concentration of Bcl-2, and (2) YC137 has a poor binding affinity in our binding assay conditions, and consequently, it is possible that the binding affinity of YC137 was underestimated. The effectiveness of this inhibitor in hematopoietic precursors that become dependent on Bcl-2 for survival suggests that the sensitivity to Bcl-2 inhibitors will be given not only by the levels of Bcl-2 but also the contribution of this antiapoptotic protein to the overall survival of particular tumor cells. Consistently, apoptosis can be induced in a number of tumor cell lines by decreasing the amount of Bcl-2 protein (4, 29). Anticancer drugs used in chemotherapy for tumors and leukemias cause severe toxicity in normal tissues, leading to side effects such as myelosuppression (30). Thus, it is of particular interest our finding that normal cells, including a small intestine epithelial cell line (FHs), myoblasts, PBMCs, and CD34<sup>+</sup> hematopoietic progenitors, are not sensitive to YC137. A likely explanation is that Bcl-2 is either absent or not relevant for survival in these cell systems. Consistently, FHs cells do not express Bcl-2 protein (data not shown), which is in agreement with data showing that Bcl-2 is absent in the transcripts of the small intestine (31). Additionally, it has been described that Bcl-2 expression is limited to a small proportion (1% to 4%) of neonatal and adult primary muscle cells in culture (32) and that other Bcl-2 family members, such as Mcl-1 and Bcl-x<sub>L</sub>, instead of Bcl-2, are critical in the regulation of apoptosis in peripheral blood lymphocytes (33, 34). Furthermore, several authors have shown that in quiescent hematopoietic progenitors, Bcl-2 is not expressed or does not contribute significantly to the survival of this cell population (35, 36). This is the first study that shows the specificity of a Bcl-2 inhibitor for tumor cells as compared with a variety of normal primary cells.

Chronic myelogenous leukemia represents the first human malignancy to be successfully treated with a small molecule inhibitor specific for a tyrosine kinase (17). However, clinical resistance to this inhibitor has been reported in a number of patients, which led to the notion that the effectiveness of other selective inhibitors may be hampered by the presence of resistant tumor cells. We have described a variant of the MB435B cell line that is resistant to YC137-induced apoptosis. This resistant subline has reduced levels of Bcl-2 attributable to down-regulation of the HER2-Stat3 transcriptional pathway, which contributes to chemosensitivity. In support of this, reduced expression of Bcl-2 by antisense oligonucleotides has been shown to sensitize tumor cells to chemotherapeutic drugs (3, 37). We demonstrated previously that Bcl-2 is transcriptionally regulated by Stat3 in MB435B cells (19). However, this pathway seems to be triggered by EGFR, and we show here that resistant cells down-regulate the expression of HER2 but not EGFR. This result may be explained by the formation of receptor complexes between these two members of the EGFR family, which allow the participation of HER2 in apoptosis regulation, because no direct ligand appears to exist for HER2 (38). Trastuzumab, used for the treatment of some forms of breast cancer, is another example of a gene-based cancer drug.
monoclonal antibody binds HER2 and induces receptor internalization and degradation, inhibits cell cycle progression, and sensitization to chemotherapy-induced apoptosis (39, 40). We show that trastuzumab down-regulates the Stat3-dependent expression of Bcl-2 in MB435B cells, and consistent with our previous data, these cells become more resistant to YC137. This novel result supports the relevance of Bcl-2 levels in the efficacy of Bcl-2 inhibitors and sheds light on the mechanisms by which trastuzumab may modulate the apoptotic response to chemotherapy in tumor cells. It also identifies other molecular targets, such as Stat3 and Bcl-2, that can lead to a rational design of therapies that increase drug sensitivity.

In conclusion, we have described a small molecule inhibitor of Bcl-2, YC137, and showed for the first time that a Bcl-2–specific inhibitor is able to kill selectively tumor cells that overexpress or depend on this antiapoptotic protein for survival but has no effect on a variety of primary cells. We also describe that cancer cells may develop resistance to YC137. Resistant cells reduce the levels of Bcl-2 and become more sensitive to chemotherapy. These data support the relevance of Bcl-2 levels in the efficacy of Bcl-2 inhibitors and sheds light on the mechanisms by which trastuzumab may modulate the apoptotic response to chemotherapy in tumor cells.
